Call to restrict neonicotinoids

Neonicotinoids are the most widely used insecticides in the world (1). They are applied to a broad range of food, energy, and ornamental crops, and used to combat pest control (2). Because they are neurotoxins, they are highly toxic to insects (3), a group of organisms that contains the majority of the described life on Earth, and which includes numerous species of vital importance to humans such as pollinators and predators of pests (3). Neonicotinoids have proved to be highly persistent in the environment, such that substantial residues are commonly found in soils, wildflowers, streams, and lakes (4). One recent study found neonicotinoids in 75% of honey samples collected from around the world (5). Hundreds of independent scientific studies have been performed to assess their impacts on beneficial organisms such as bees, aquatic insects, butterflies, and predatory beetles (4, 6).

It is the view of the undersigned scientists that the balance of evidence strongly suggests that these chemicals are harming beneficial insects and contributing to the current massive loss of global biodiversity. As such, there is an immediate need for national and international agreements to greatly restrict their use, and to prevent registration of similarly harmful agrochemicals in the future. On 28 April, the European Parliament voted for a complete and permanent ban on all outdoor uses of the three most commonly used neonicotinoid pesticides (7). With the partial exception of the province of Ontario,

Canada (8), governments elsewhere have failed to take action.

Failure to respond urgently to this issue risks not only the continued decline in abundance and diversity of many beneficial insects, but also the loss of the services they provide and a substantial fraction of the biodiversity heritage of future generations.

RESEARCH

NEONICOTINOIDS

A worldwide survey of neonicotinoids in honey

E. A. D. Mitchell,^{1,2*} B. Mulhauser,² M. Mulot,^{1,†} A. Mutabazi,³ and J. P. G. Béguin¹

Growing evidence for global pollinator decline is causing concern for ecosystem health, food security, and conservation and ecosystem services maintenance. Neonicotinoids have been identified or suspected as a key factor responsible for this decline. We conducted a worldwide survey of the global exposure of pollinators to neonicotinoids by analyzing 1,440 samples of honey from across the world. We found at least one of five tested neonicotinoids (acetamiprid, clothianidin, imidacloprid, thiacloprid, and thiamethoxam) in 95% of samples. At least 55% of samples contained two or more of these compounds. The average concentration was 1.8 ng/g over four or five. Our results confirm the exposure of bees to neonicotinoids is widespread and occurs throughout the world. The coexistence of neonicotinoids and other pesticides may increase their potential to cause harm to pollinators. However, the concentrations detected were well below the maximum residue level authorized for human consumption (average \pm standard deviation: 1.8 \pm 0.56 nanograms per gram).

Neonicotinoids are currently the most widely used class of insecticides worldwide (1). These pesticides are increasingly prevalent in terrestrial and aquatic environments (2, 3). Neonicotinoids are taken up by plants and transported to all organs, including flowers,

least frequent in South America and Oceania (table S4 and Fig. 1). Frequency of occurrence was highest for imidacloprid (51% of samples) and lowest for clothianidin (16%). Maximum and average concentrations among positive samples were highest for acetamiprid and thiacloprid (table S5).

The frequency of occurrence of individual neonicotinoid in honey samples and their relative contribution to the overall neonicotinoid concentration varied among the regions (Fig. 1). Imidacloprid dominated overall concentrations in Africa and South America, thiacloprid in Europe, acetamiprid in Asia, and thiamethoxam in Oceania and North America (Fig. 1), reflecting regional differences in usage of specific pesticide types. In all regions, at least one neonicotinoid was recorded in at least 25% of samples, and three neonicotinoids (thiamethoxam, imidacloprid, and clothianidin) were recorded in at least 50% of samples in North America (table S6).

The total concentration of the five measured neonicotinoids was, on average, 1.8 ng/g in positive (i.e., contaminated) samples and reached a maximum of 56 ng/g over all positive samples (table S4). This average concentration lies within the bioactive range (27, 28), causing deficits in learning (29, 30), behavior (31), and colony performances (8, 32) in honey bees (table S8). As for

Aucun nouveau pesticide ne doit être autorisé avant d'avoir des méthodes reconnues sur le plan international pour évaluer les effets sublétaux et chroniques de ces produits (...) cela concerne également l'utilisation combinée de plusieurs pesticides (...)

L'utilisation de trois néonicotinoïdes particulièrement toxiques pour les abeilles (...) pour lesquels un moratoire temporaire est en vigueur (...) est à interdire de manière globale.

DÉBUT SUR CE SUJET. L'organisation suisse des apicultrices et apiculteurs est depuis longtemps déjà active dans ce domaine et émet les demandes suivantes:

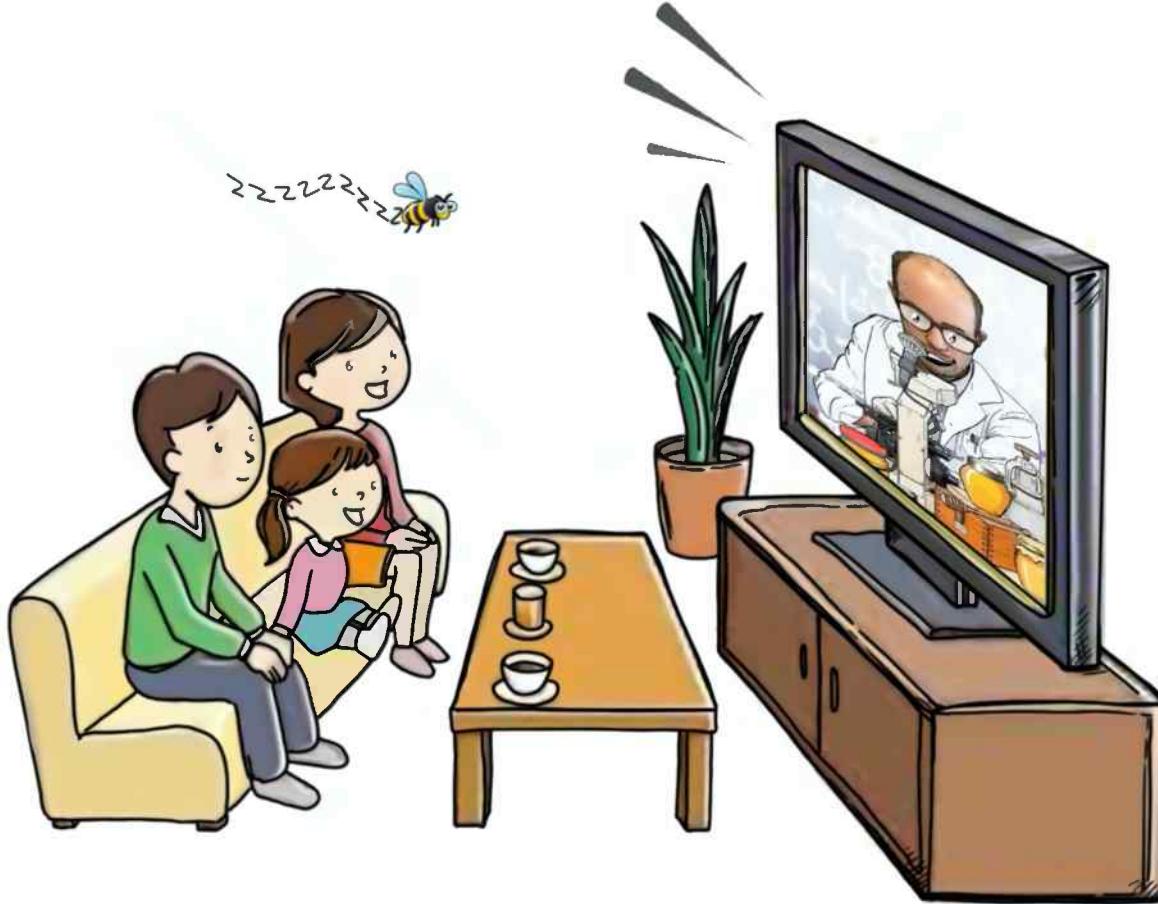

L'utilisation de pesticides agissant de manière systémiques devrait être autorisée uniquement pour des plantes qui ne font pas partie de la flore mellifère.

clothianidine), pour lesquels un moratoire temporaire est en vigueur pour certaines applications, est à interdire de manière globale.

Dans les cultures butinées par les abeilles, les pesticides doivent être appliqués en dehors des heures de vol des abeilles.

abeilles.

Although neonic pesticides are the world's widest used insecticides new research has led the UK and the European Union to move towards a total ban on the bee-harming products.

With Europe pointed towards a total ban on all neonic pesticides to protect bees don't you think Canada should too?

Take action now The decision reverses the government's previous position and is justified by recent new evidence showing neonicotinoids have contaminated the whole landscape and cause damage to colonies of bees. It also follows the revelation that [75% of all flying insects have disappeared](#) in Germany and probably much further afield, a discovery Gove said had shocked him.

Gove said the evidence of neonicotinoids' harm to pollinators has grown stronger since 2013, including a landmark field trial published in July that showed [neonicotinoids damage bee populations](#), not just individual insects, and a [global analysis of honey revealing worldwide contamination](#) by the insecticides.
